(54) Title: TRANSLUMINAL DEVICES, SYSTEMS AND METHODS FOR ENLARGING INTERSTITIAL PENETRATION TRACTS

(57) Abstract

This invention is methods, apparatus, and systems for enlarging interstitial penetration tracts which have been formed between blood vessels or elsewhere within the body of a mammalian patient. Included are de-bulking type tract enlarging systems (10, 10a), dilation-type tract enlarging systems (10b), tissue-sclicing-type tract enlarging systems (10c), and two-catheter-type tract enlarging systems (17).

TRANSLUMINAL DEVICES, SYSTEMS AND METHODS FOR ENLARGING INTERSTITIAL PENETRATION TRACTS

Field of the Invention

5 The present invention relates generally to medical devices and methods, and more specifically to transluminal devices, systems and methods which are useable to enlarge interstitial tracts (e.g., man made puncture tracts or small passageways) which extend between two (2) anatomical conduits (e.g., blood vessels) or otherwise
10 through tissue(s) within a mammalian body.

Background of the Invention

 Applicant has devised several new medical procedures wherein passageway-forming catheters are advanced into anatomical
15 conduits (e.g., blood vessels) and are used to create one or more interstitial passageways which extend outwardly, from the conduit in which the catheter is positioned, to another conduit or anatomical structure. Some of these procedures may be used to form flow-through passageways between the anatomical conduit (e.g., blood
20 vessel) in which the passageway-forming catheter is positioned, and another anatomical conduit (e.g., another blood vessel) or a different location on the same anatomical conduit (e.g., a downstream site on the same blood vessel). Alternatively, these procedures may be used to form access passageways between the anatomical conduit (e.g.,
25 blood vessel, urethra, fallopian tube, etc..) and another anatomical structure (e.g., a tumor, organ, muscle, nerve, etc.).

 In at least some of applicant's procedures, the interstitial passageway(s) are initially formed by advancing a tissue-penetrating element (e.g., a small diameter needle or a flow of tissue-penetrating
30 energy) from the passageway-forming catheter, through the wall of the anatomical conduit in which the catheter is positioned, and into

the target location. In some cases, the interstitial passageway which is formed by the initial passage of the tissue-penetration element from the passageway-forming catheter is of relatively small diameter—and must subsequently be enlarged (e.g., debulked, 5 dilated, expanded, stretched) to accommodate the desired flow of biological fluid (e.g., blood) or passage of other substances/ devices therethrough.

In particular, as described in applicant's earlier-filed United States Patent Applications Serial No. 08/730,327 and 08/730,496, 10 such enlargement of the initially formed interstitial passageway (e.g., penetration tract) may be particularly important when the procedure is being performed to by-pass an obstruction within a coronary artery. For example, in some of applicant's procedures, a primary interstitial passageway is formed between an obstructed coronary artery and an 15 adjacent coronary vein, such that blood will flow from the obstructed artery into the adjacent coronary vein. In such applications, the arterial blood which enters the adjacent coronary vein through the primary interstitial passageway is allowed to retroperfuse the ischemic myocardium by retrograde flow through the coronary vein. 20 In other of applicant's procedures, one or more secondary interstitial passageways are formed between the coronary vein into which the arterial blood has flowed and the obstructed artery (or some other coronary artery) to allow arterial blood which has entered the coronary vein to reenter the obstructed artery (or some other 25 coronary artery), after having bypassed the arterial obstruction. Thus, in either of these interventional procedures, it is important that the primary and/or secondary interstitial passageway(s) remain patent and sufficiently large in diameter to support the continued flow of arterial blood to the myocardium. However, the task of enlarging the 30 small diameter interstitial passageway(s) (e.g., puncture tracts) formed by the initial passage of the tissue-penetrating element

presents numerous technical challenges.

Although the prior art has included a number of catheter-based devices which may be used to enlarge or remove obstructive matter from the lumen of a blood vessel or other anatomical conduit (e.g., a blood vessel). These devices include; atherectomy catheters, embolectomy catheters, balloon angioplasty catheters, laser ablation catheters, etc. However, these prior art lumen-enlarging/lumen-clearing devices have typically not been intended for use in small diameter puncture tracts which diverge at an angle from the conduit lumen in which the catheter is located, as is typically the case in applicant's above-summarized interventional procedures.

Accordingly, there exists a need for the design and development of a new device, system and method for enlarging interstitial penetration tracts (e.g., man-made punctures or small passageways) which extend between adjacent anatomical conduits (e.g., blood vessels) within a mammalian body.

SUMMARY OF THE INVENTION

The present invention provides devices which are useable in combination with each other (i.e., as a system) to enlarge an interstitial tract (e.g., a small diameter penetration tract through tissue) which extends from a blood vessel or other anatomical conduit of the body. The devices and systems of the present invention generally fall into three (3) major classifications--1) debulking-type tract enlargement systems, 2) dilating-type tract-enlargement systems, and 3) slicing-type tract enlargement systems.

In accordance with the invention, one debulking-type tract enlargement system (referred to herein as an "advancable" debulker) generally comprises: a) an elongate, pliable, tubular sheath sized for

insertion into the lumen of an anatomical conduit from which the interstitial tract extends, said sheath having a lumen which extends longitudinally therethrough; b) a counter-traction member which is advanceable, i.) through the lumen of the tubular sheath and ii.) at least partially through the interstitial tract, such that the countertraction member engages or becomes positioned in relation to tissue which lies adjacent the interstitial tract to thereafter exert proximally-directed force upon such tissue; and, c) a debulker (e.g., a tissue removing apparatus or flow of energy) which is advanceable out of the lumen of the sheath in a distal direction (i.e., substantially opposite the proximally-directed force being exerted by the counter-traction member) to remove tissue from the area adjacent the tract.

Further in accordance with the invention, there is provided another debulking-type tract enlargement system (referred to herein as a "retractable" debulker) generally comprises: a) an elongate, pliable, tubular sheath sized for insertion into the lumen of an anatomical conduit from which the interstitial tract extends, said sheath having a lumen which extends longitudinally therethrough, and b) a pull-back debulker (e.g., a tissue-removing apparatus or flow of energy) which is i.) initially advanceable out of the lumen of the sheath in a distal direction so as to pass through the penetration tract which is to be enlarged, and ii.) thereafter retractable in the proximal direction so as to remove tissue which lies adjacent the interstitial tract, thereby enlarging the interstitial tract.

Still further in accordance with the invention, there is provided a dilating-type tract enlargement system (referred to herein as a "dilating" system) which generally comprises: a) an elongate, pliable, tubular sheath sized for insertion into the lumen of an anatomical conduit from which the interstitial tract extends, said sheath having a lumen which extends longitudinally therethrough, and b) a dilator

(e.g., an elongate member) having at least one tissue-dilating member (e.g., a tapered, frusto-conical member, balloon or radially deployable member(s)) formed thereon, such dilator being advanceable into the penetration tract which is to be enlarged, and
5 is subsequently useable to dilate such penetration tract, thereby resulting in the desired enlargement thereof. A positioning surface may be formed on the dilator to abut against tissue which lies adjacent the passageway in a manner which will enable the operator to determine that the dilator has been advanced to its desired
10 position and is properly located to allow the dilate the interstitial tract as desired.

Still further in accordance with the invention, there is provided a slicing-type tract enlargement system (referred to herein as a "tissue-slicing" system) which generally comprises a) an elongate
15 shaft which is advanceable through the interstitial tract, and b) at least one tissue slicing member which extends or is extendable from the shaft to incise or cut tissue which lies adjacent the interstitial tract as the shaft is advanced and/or retracted through the tract. In some embodiments, the tissue slicing member(s) may be initially disposed
20 in a radially compact configuration which is flush with, or only slightly protrusive beyond, the outer surface of the shaft, thereby allowing the shaft to be advanced through the interstitial tract without cutting or disrupting the surrounding tissue. Thereafter, the tissue slicing member(s) is/are shifted to a radially expanded configuration wherein
25 such tissue-slicing member(s) extend or protrude laterally from the shaft so as to slice, incise or cut at least some of the tissue which surrounds the tract. The tissue-slicing member(s) need not be concentric about the shaft, but rather may be of substantially flat configuration so as to create a defined incision or cut in the tissue.
30 Moreover, the tissue-slicing member(s) may be configured so as not to completely sever and *remove* tissue in the manner of the above-

sumarized debulking-type embodiment, but rather may simply form a slit or incision adjacent the tract such that the surrounding tissue will continuously or intermittantly separate to allow flow of fluid (e.g., blood) therethrough.

5 Still further in accordance with the invention, there is provided a two-catheter type tract enlarging system (referred to herein as a "two-catheter" system) which is specifically useable to enlarge an interstitial tract or passageway which has been formed between two adjacent anatomical conduits (e.g., blood vessels). Such two-
10 catheter system generally comprises a) a first catheter having a tract-enlarging apparatus (e.g., a debulker, dialtor or tissue-slicing member of the above-described nature) which is advancable from an opening at or near the distal end of that catheter, and b) a second catheter which has an anvil member (e.g., an abutable surface or receiving
15 cavity) which is sized and configured to correspond with the leading end of the tract-enlarging apparatus of the first catheter. The first catheter is positioned in one of the anatomical conduits, and the second catheter is positioned in the other anatomical conduit, with its anvil member located next to the interstitial tract or passageway
20 which is to be enlarged. Thereafter, the tract enlarging apparatus is advanced through the tract or passageway until it registers with (e.g., abutts against or is received with) the anvil member of the second catheter. As the tract enlarging apparatus is being advanced, the anvil member serves to provide counterforce against the tissue
25 adjacent the initially formed tract or passageway so as to prevent unwanted protrusion or "tenting" of the tissue into the second anatomical conduit, and to ensure efficient cutting of the tissue in cases where a debulking or tissue slicing type tract enlarging apparatus is used.

30 Still further in accordance with the invention, either the debulking-type, dilating type, tissue-slicing type or two catheter type

tract enlargement systems of the present invention may incorporate a guidewire lumen which extends longitudinally through the i.) tract enlarging member (e.g., debulker, dilator or tissue slicing member) to permit the tract enlarging member to be advanced over a small
5 guidewire which has previously been passed through the penetration tract which is to be enlarged. Thus, the provision of such guidewire lumen may permit the system to be used to dilate penetration tracts which are of extremely small diameter, or which have become substantially closed off due to constriction of the surrounding tissue,
10 provided that a guidewire was previously inserted through such penetration tract.

Still further in accordance with the invention, energy such as radio-frequency energy or electrical resistance heat may be applied to the tract enlarging member (e.g., debulker, dilator, or tissue slicing
15 member) to enhance the tract-enlarging efficiency thereof.

Still further objects and advantages of the present invention will become apparent to those of skill in the relevant art, upon reading and understanding of the following detailed description of the invention and the accompanying drawings.

15 Figure 18c is a distal end view of the alternative tissue cutting tip of Figure 18a.

Figure 19 is a schematic showing of two adjacent blood vessels having a penetration tract formed therebetween, and a two-catheter tract enlarging system of the present invention operatively disposed therein to enlarge the penetration tract.

20

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

25 The preferred embodiments and examples described in the following paragraphs, and shown in the accompanying drawings, should be considered as exemplars, rather than limitations on the devices, systems and methods of the present invention.

30 The particular embodiments described in detail below include debulking-type tract enlarging systems 10 and 10a, dilating-type tract enlargement systems 10b, and tissue-slicing-type tract enlarging systems 10c.

A. Debulking-Type Systems

Generally, the debulking-type systems 10, 10a serve to remove (e.g., cut, sever, ablate, vaporize, etc.) tissue which surrounds or lies adjacent to the initially formed interstitial tract thereby enlarging the tract. The description set forth in the following paragraphs includes a distally advanceable debulking-type system 10 as well as a proximally retractable debulking-type system 10a.

1. Advanceable Debulking-Type Systems

Figures 1-9 show a preferred, distally-advanceable debulking-type tract enlarging system 10 which is useable to enlarge a penetration tract. As shown in detail in Figures 4-8a, this distally advanceable debulking system 10 generally comprises a) a subselective sheath 12, b) a distally-advanceable debulker 14 which is passable out of the subselective sheath, in a distal direction DD, and a counter-traction member 16 which is advanceable through the penetration tract ahead of the debulker 14, and engageable with tissue adjacent the tract to exert a counter-force (i.e. a force directed in the proximal direction PD) upon the tissue which is to be severed by the distally advancing debulker 14. It is also to be understood that the counter-traction member 16 may simply be positioned adjacent the tissue such that it does not actually exert force against the tissue until the debulker 14 is advanced into contact with the tissue, at which time the tissue will then be compressed between the debulker and the counter-traction member 16 as the debulking procedure is performed.

Subselective Sheath

The subselective sheath 12 of the embodiment shown in the drawings comprises a flexible tube which is sized to be advanceable into the anatomical conduit from which the interstitial penetration tract extends. With particular reference to the showings of Figure 4, 4c and 6, the preferred subselective sheath 12 comprises inner wall 30

preferably formed of formed of polytetrafluoroethylene (PTFE), an outer wall 32 preferably formed of polyether block amide polymer (e.g., Pebax™), and a braid 34 captured between inner 30 and outer 32 walls, such braid 34 terminating distally at a location which is approximately 2-10 mm from the distal end of the sheath 12. In this manner, there is defined a non-braided distal portion 36 of approximately 2-10 mm and a braided proximal portion 38. The presence of the braid 34 within the proximal portion 38 of the sheath 12 enhances its strength and resistance to crimping or kinking, while the non-braided distal portion 36 of the sheath 12 remains soft and pliable to avoid injury or damage to the walls of blood vessels or other tissues, as the sheath 12 is advanced. For use in coronary blood vessels, the sheath 12 will preferably have an outer diameter of 0.050-0.150 inch and an inner lumen diameter of 0.040-0.140 inch.

In some embodiments, the subselective sheath 12 may have lumen which curves laterally and exits through an outlet port formed in the sidewall of the sheath 12. Such side outlet sheath (not shown) may be advanced to a position where the side outlet aperture is in direct alignment with the penetration tract PT which is to be enlarged. Thereafter, the debulker 14 may be advanced out of the side outlet aperture and directly through tissue which surrounds the penetration tract PT.

Advanceable Debulker

The debulker 14 of the embodiment shown in the drawings comprises a rotating tissue cutter which, when advanced in the distal direction and concurrently rotated, will sever and remove a cylindrical mass of tissue which surrounds the penetration tract. With particular reference to the showings of Figures 7 and 7a, this preferred debulker 14 comprises a flexible tube 40 which has a lumen 44 extending longitudinally therethrough, and an annular cutting member 42 mounted on the distal end thereof. The annular cutting

member 42 has a sharpened leading edge 46 and a hollow bore 48 which extends therethrough. The cutting member 42 is mounted securely on the distal end of the tube, preferably such that the bore 46 of the annular cutting member 42 is in direct axial alignment with the lumen 44 of the tube 40, and the outer surface of the cutting member 42 is flush with the outer surface of the tube 40. The tube 40 is preferably formed of a flexible plastic such as polyether block amide polymer (e.g., Pebax™), and the cutter member 42 is preferably formed of a rigid material such as stainless steel. In embodiments intended for use in coronary blood vessels, this debulker 14 will preferably have an outer diameter of 0.05-0.13 inches and an inner (lumen) diameter of 0.04-0.12 inches. A plurality of bearing members 50 may be mounted at spaced-apart locations within the lumen 44 of the debulker 14 to facilitate rotation of the debulker 41 about a central shaft (e.g., the shaft 60 of the countertraction member 16). A drive motor/handpiece 22 may be mounted on the proximal end of the debulker 14, as shown in Figures 1 and 7. This drive motor/handpiece 22, when actuated, will rotationally drive the debulker 14, at a suitable rate of rotation to facilitate the desired severing of tissue. In applications where the debulker 14 is being used to sever soft tissue, it is preferable that the motor/handpiece 22 be capable of driving the debulker 14 at 60-300 revolutions per minute. One example of a commercially available drive motor/handpiece 22 which may be used is the MDV Motor Drive Unit manufactured by DVI, Inc.

Counter-traction Member

The counter-traction member 16 of the embodiment shown in the drawings serves to pass through the interstitial tract to be enlarged, ahead of the debulker, and prevents unwanted protrusion or "tenting" of the tissue into the adjacent anatomical conduit, thereby enhancing the tissue cutting efficiency of the debulker. With

particular reference to the showings of Figures 4, 4a, 8 and 8a, the preferred counter-traction member 16 comprises an elongate, pliable shaft 60 having a dilator/tissue-engaging member 62 mounted on the distal end thereof, and a guidewire lumen 67. The tract dilator/tissue

5 engaging member 62 comprises a frustoconical body 68 and a cutting-engagement plate 64 formed on the proximal end thereof. The proximal surface 66 of the cutting-engagement plate 64 is disposed in a plane P which is substantially perpendicular to the longitudinal axis LA of the shaft 60. The frustoconical portion is

10 preferably formed of soft plastic such as polyether block amide polymer (e.g., Pebax™) and the cutting/engagement plate 64 is preferably formed of hard material such as polycarbonate or stainless steel. As shown in the exploded view of Figure 8a, a cavity 73 may be formed in the proximal end of the dilator/engagement plate 62,

15 including a shaft receiving portion 74 and an annular groove 70. The distal portion 65 of the cutter/engagement plate 64 is inserted into cavity 73 such that an annular shoulder 72 formed about the proximal portion 65 will frictionally engage a corresponding annular groove 70 formed about the interior of the cavity 73, thereby holding the

20 cutting/engagement plate 64 in fixed position on the distal end of the dilator/engagement member 62. The distal end of the shaft 60 is then inserted through the bore 67 of the cutting/engagement plate 64 until it bottoms out in the shaft receiving portion 74 of the cavity 73. An adhesive or thermal compression bonding may be used to securely

25 hold the shaft in contact with the dilator/engagement member 62. Additionally or alternatively, the proximal portion 65 of the cutting/engagement plate 64 may act as a ferrule, exerting radial inward pressure against the shaft to frictionally hold the shaft in its inserted position within the cavity. The counter-traction member 16

30 also acts to protect the adjacent vessel or luminal anatomical structure from iatrogenic trauma (e.g., perforation, laceration) as the

debulker is advanced.

It is to be appreciated that various other types of tissue-engaging members may be utilized in addition to, or as an alternative to the particular counter-traction member 16 shown in Figures 1 -8. Some examples of alternative types of countertraction members 16a, 16b, 16c are shown in Figures 9a-9c and 11 a-11 h.

With reference to Figures 9a-9c one alternative counter-traction member 16a comprises a telescoping shaft 80 formed of a distal shaft portion 80' and a proximal shaft portion 80", having a plurality of radially expandable members 82 disposed about the shaft 80, as shown. Preferably, a guidewire lumen (not shown) extends longitudinally through the shaft 80. Each radially expandable member 82 has a distal end which is affixed to the distal shaft portion 80' and a proximal end which is affixed to the proximal shaft portion 80". As shown in Figure 9a, when the distal shaft portion 80' is fully advanced in the distal direction, the radially expandable members will be in a radially collapsed configuration of diameter D, which is sufficiently small to be advanceable through the previously formed penetration tract. Thereafter, as shown in Figures 9b and 9c, the distal shaft portion 80' may be retracted into the proximal shaft portion 80" to cause the radially expandable members to bow or expand outwardly. Thus, when the distal shaft portion 80' is partially retracted the radially expandable members 82 may assume a partially expanded configuration of diameter D_2 when the distal shaft member 80' is fully retracted the radially expandable members 82 will assume a fully expanded configuration of diameter D_3 .

Referring to Figures 11 a-11 d, another alternative counter-traction member 16b comprises an elongate shaft 90 which has a guidewire lumen 92 and a balloon inflation/deflation lumen 94 extending therethrough, and a balloon 96 mounted thereon. With the balloon in its deflated state as shown in Figure 1 Oa, the shaft 90 is

advanceable over a guidewire and through the penetration tract PT which is to be enlarged. After the balloon 96 has emerged out of the opposite end of the penetration tract PT, inflation fluid is injected through the inflation/deflation lumen 94 to inflate the balloon 96 as shown in Figure 10c. As described in more detail herebelow, the inflated balloon 96 will abut against and engage the tissue which surrounds the penetration tract PT, and will exert proximally directed force on such tissue while the debulker 14 is advanced through the tissue. As shown in Figure 1 Od, after the tissue has been fully severed, the shaft 90 will be fully retracted into the lumen 44 of the debulker 14 and the cutting surface 46 of the annular cutting member 42 will abut against a reinforced region 98 of the balloon. Such reinforced region 98 is sufficiently resistant to cutting or puncture to prevent the annular cutting member 42 from bursting or penetrating through the wall of the balloon 96.

Referring to Figures 11e-11 h, there is shown yet another counter-traction member 16c which comprises an elongate shaft 150 having a plurality of resilient or spring loaded, outwardly splayable members 160 which are attached at their distal ends to the shaft 150. The proximal ends of the splayable members 160 are biased to a radially expanded configuration as shown in figures 11f-11h, but are initially compressible to a radially compact configuration wherein they may be received within the lumen 44 of the debulker, as shown in Figure 11 e. Initially, with the splayable members 160 are placed in their radially compact configuration and retracted at least partially within the lumen 44 of the tubular member 40 of the debulker 14. After the system has been inserted in the body and positioned adjacent the interstitial tract to be enlarged, the shaft 150 is advanced in the distal direction to drive the splayable members 160 through the interstitial tract. As the proximal ends of the splayable members emerge from the distal end of the interstitial tract, they will

spring outwardly to their radially expanded configuration and will engage the tissue adjacent the distal end of the tract. Thereafter, proximally directed pressure may be applied to the shaft as the debulker 40 is advanced in the distal direction. This results in the
5 desired counter-traction on the tissue being severed by the annular cutting member 42. At the end of the tract enlarging procedure, the leading edge 46 of the annular cutting member 42 will be nested within and in contact with the splayable members 160, as shown in Figure 11 h. In this manner, as will be more fully appreciated after
10 reading the explanation of the detailed operation of the device set forth herebelow, the tissue which has been severed from the area surrounding the interstitial tract will be received within the lumen 44 of the debulker, for subsequent removal from the body.

Operation of the Distally Advanceable Debulking-type System

15 Prior to operation, the system 10 is assembled in the manner shown in Figure 5a, such that the shaft 60 of the counter-traction member 16 is slidably and rotatably disposed within the lumen 44 of the debulker 14 (i.e. extending through the bearings 50 located within the lumen 44 of the debulker 14) and the countertraction member 16
20 and debulker 14 are positioned within the lumen 31 of the sheath 12. This system 10 may then be utilized to enlarge a small penetration tract PT which has been formed between an anatomical conduit and some other anatomical conduit or cavity within the body. For purposes of illustrating and explaining the operation of the present
25 invention, Figures 3a-3d show a specific coronary revascularization procedure wherein an interstitial passageway is to be formed between a coronary vein CV and an adjacent coronary artery CA, to permit arterial blood to flow into the coronary vein CV.

30 With reference to Figures 3a-3d, after an interstitial penetration tract PT has been formed between a coronary artery CA and coronary vein CV, a small guidewire GW is passed through such

penetration tract PT. The guidewire GW is passed, proximal end first, into the distal end of the guidewire lumen 67 which extends through the counter-traction member 16. With the debulker 14 and countertraction member 16 disposed within the lumen 31 of the subselective sheath 12, the system 10 is advanced over the guidewire GW until the distal end of the subselective sheath 12 becomes positioned within the coronary vein CV at a location approximately 0.10 inch (i.e., 2-3 mm) from the penetration tract PT. Thereafter, as shown in Figure 3, the counter-traction member is further advanced such that the dilator/engagement member 62 will pass through the penetration tract PT and into the coronary artery CA. As the dilator/engagement member emerges into the lumen of the coronary artery CA the tissue surrounding the penetration tract PT will elastically retract about the distal portion of the shaft and the proximal surface 66 of the cutting/engagement plate 64 will abut against the coronary artery wall immediately adjacent the opening of the penetration tract PT into the coronary artery CA. Thereafter, proximally directed pressure is applied to the counter-traction member 16 while concurrently advancing the debulker 14 in the distal direction, as shown in Figure 3a. As the advancing debulker 14 comes into contact with the tissue which surrounds the penetration tract PT, the drive motor/handpiece 22 is actuated so as to rotate the debulker at approximately 60-300 RPM. As shown in Figure 3b, this causes the sharpened leading edge 46 of the cutting member 42 to cut a cylindrical bolus of tissue as the rotating debulker 14 continues to advance. The application of proximally directed pressure on the counter-traction member 16 concurrently with the distally directed advancement of the debulker 14 prevents the surrounding tissue from "tenting" and enhances the cutting efficiency of the debulker 14. Also, because the tissue which is being severed is located directly behind the cutting/engagement plate 64, the severed bolus of tissue

will be prevented from escaping into the coronary artery CA, and will be forced into the lumen of the debulker 14 whereby it may be extricated and removed from the body along with the debulker 14, as illustrated in Figure 3c. This results in the formation of an enlarged
5 bloodflow passageway EBP, as desired.

As shown in Figure 3d, and in accordance with applicants methodology described in earlier-filed United States Patent Applications Serial No. 08/730,327 and 08/730,496, one or more
10 embolic blockers B or other flow-blocking means may be utilized to prevent arterial blood which enters the coronary vein CV through the enlarged bloodflow passageway EBP from flowing in the venous return direction, and to cause such arterial blood to flow through the coronary vein CV in the retrograde direction, thereby bypassing the obstruction OB located in the adjacent coronary artery CA.

15

2. Retractable Debulking-type Systems

Figures 12a-12b show an example of a retractable debulking-type tract enlargement system 10a, of the present invention. This system 10a comprises a proximal counter-force
20 member 112 in combination with a retractable debulker 14a, as shown in Figures 12a and 12b.

Proximal Counter-force Member

The proximal counter-force member 112 comprises a tube
25 having a lumen (not shown) which extends longitudinally therethrough and an annular cutting/engagement plate 100 formed on the distal end thereof. The annular cutting/engagement plate 100 serves to engage a pull-back tissue cutter formed on the proximal end of the retractable debulker 14a. In embodiments where the
30 retractable debulker is rotatable, a plurality of bearings 50 of the type described hereabove may be coaxially disposed at spaced apart

locations within the lumen of the proximal counter-force member 112.

Retractable Debulker

5 The retractable debulker 1 4a of this embodiment comprises a shaft 102 having a flexible frusto-conical dilator 104 formed thereon, and an annular cutter member 106 mounted on the proximal end of the dilator 104, as shown. The frusto-conical dilator 104 may be constructed and configured the same as the frustoconical body 68 described hereabove. The annular cutting memebr 106 may be
10 constructed and configured the same as the annular cutting member 42 of the first embodiment described hereabove. This annular cutting member 106 has a sharpened proximal edge 108 which will sever tissue when retracted therethrough. A guidewire lumen(not shown) extends longitudinally through the shaft 102 and through the
15 frusto-conical dilator. Optionally, the retractable debulker 1 4a may be rotatably driven by a drive motor/handpeice 22 as described hereabove.

Operation of the Retractable Debulker Type System

20 Prior to operation, this retractable debulking type system 1 Oa is assembled such that shaft 100 the retractable debulker 1 4a is slidably and (and in some cases rotatably) disposed within the lumen of the proximal counter-force member 112. In embodiments wherein the debulker 14a is rotatable, the shaft 102 will extend through any
25 bearings 50 disposed within the lumen of the counter-force member 112. The shaft 102 may initially be retracted such that the proximal sharpened edge 108 of the annular cutter 106 is in abutment with the annular cutting plate 100. The counter-force member 1 12 and retractable debulker 14a are positioned within the lumen 31 of a
30 subselective sheath 12 as described hereabove. This system 1 Oa may then be utilized to enlarge a small penetration tract PT which

has been formed through the sidewall of and extending outwardly from an anatomical conduit of the body, and through which a guidewire has been inserted.

5 The guidewire GW which extends through the penetration tract is inserted into the distal end of the guidewire lumen (not shown) of the retractable debulker 1 4a. The subselective sheath 12 having the counterforce member 1 12 and retractable debulker positioned therewith, is maneuvered into the anatomical conduit from which the penetration tract extends. Thereafter, the shaft 102 of the retractable debulker 1 4a is advanced such that the dilator 104 is forced through the penetration tract. After the sharpened proximal edge 108 of the retractable debulker 14a has emerged out of the opposite end of the penetration tract, the tissue which surrounds the penetration tract will elastically constrict about the shaft. The counter-force member 112 10 is then advanced until the distal lo annular cutting plate 100 is in abutment with the wall of the portion of the wail of the anatomical conduit which surrounds the proximal end of the penetration tract.

Thereafter, distally directed counter-force is applied to the counter-force member 112 while the retractable debulker 14a is retracted in the proximal direction. Optionally, the retractable debulker 14a may be rotated concurrently with its retraction. As the debulker 14a is retracted, the sharpened proximal edge 108 of the annular cutting member 106 will sever a generally cylindrical bolus of tissue which surrounds the puncture tract, thereby accomplishing the desired enlargement of the initially formed penetration tract. The severed bolus of tissue will be drawn into, and captured within, the lumen (not shown) of the counter-force member 112 as the sharpened proximal edge 108 of the annular cutting member 106 is retracted into contact with the annular cutting plate 100.

30 Thereafter, the counter-force member 112 (having the severed bolus of tissue contained therewithin) and the retractable debulker

14a, may be removed from the body along with the subselective sheath 12.

3. Sizing and Shaping of the Debulker to Optimize Flow Channel

In either debulking type system 10, 10a the particular geometry of the cutter member 42 can assist in creation of the optimal passage, such as the enlarged bloodflow passageway EBP of the foregoing example. For example, the annular cutting member 42 need not be of circular cross-sectional configuration as shown in Figure 7a, but rather may be of oblong or oval configuration. Such oblong or oval shape of the annular cutting member 42, when advanced through the puncture tract without rotation thereof, will form a channel of oval or oblong cross-sectional shape.

Also, as shown on Figure 4, the annular cutting member 42 may be of tapered outer diameter, such that its distal cutting edge is of a first diameter d_x and its proximal end is of a second diameter d_y . Such tapering of the annular cutting member 42 causes the tissue which is cut by the cutting edge 46 to expand as the debulker 14 is advanced, thereby resulting in a more predictable diameter of the resultant channel.

4. Optional Energy-Delivery Features which may be Incorporated into Any of these Tract-Enlarging Systems

It will be appreciated that certain types of energy (e.g., laser, radio-frequency energy, electrical resistance heat, etc.) may be delivered to a tract-enlarging apparatus such as the debulker 14, 14a and/or counter-traction member 16, 16a, 16c to enhance the tract-enlarging efficiency of the system. Specific examples of systems which incorporate such energy emitting components are shown in Figures 10a-10f.

Figures 10a-10c show one energy-emitting debulking-type system which incorporates a bipolar, energy-emitting debulker 14'. Figures 10d-10f show another energy-emitting, debulking-type system one electrode is located on an energyemitting debulker 14''' and another electrode is located on an energy-emitting counter-traction member 16'''.

With reference to the particular embodiment shown in Figures 10a-10c, the bipolar, radiofrequency debulker 14' comprises an elongate tubular member 40' having a hollow lumen 44' extending longitudinally therethrough. First and second energy-transmitting members 204a, 204b extend longitudinally through the tubular member 44', as shown in the cross sectional view of Figure 10c. A debulking electrode tip 205 is mounted on the distal end of the tubular member. Such electrode tip 205 incorporates a first radiofrequency-emitting electrode 206 and a second radiofrequency-emitting electrode 208, as shown in Figure 10b. The first energy transmitting member 204a is connected to the first electrode 206 and the second energy transmitting member 204b is connected to the second electrode 208. An annular insulator body 210 is disposed between the electrodes 204a, 204b. A bipolar radiofrequency generator 200 is connected by way of a wire 202 to the first and second energy transmitting members 204a, 204b such that a circuit is completed between the generator 200 and the respective first and second electrodes 206, 208. Thus, as the debulker is advanced in the distal direction through the interstitial passageway, the generator may be energized to cause radiofrequency current to pass between the annular distal surfaces of the first and second electrodes 206, 208, thereby effecting bipolar cutting or ablation of the tissue which surrounds the interstitial tract.

In the alternative bipolar energy-emitting system shown in Figures 10d-10f, the first electrode 206a is mounted on the distal end

of the debulker 14" and the second electrode 208a is mounted on the proximal end of the countertraction member 16", as shown. In this embodiment, the first energy transmitting member 204a extends through the tubular member 40" of the debulker 14" while the second
5 energy transmitting member 204b extends through the shaft 60" of the countertraction member 16". Here again, the first energy transmitting member 204a is connected to the first electrode 206a of the second energy transmitting member 204b is connected to the second electrode 208a. In this manner when a bipolar radiofrequency
10 generator 200 is connected to the energy transmitting members 204a, 204b, a circuit is completed between the generator and the first and second electrodes 206a, 208a such that radiofrequency current will pass between the electrodes 206a, 206b in a manner which cuts or ablates the tissue which surrounds the interstitial tract.

15 As those skilled in the art will appreciate, although bipolar embodiments are shown in Figures 10a-10f, similar monopolar embodiments may also be devised through the alternate use of a separate antenna or plate electrode which attaches to the patient's body to complete the circuit. Such monopolar embodiments may
20 utilize only a single electrode 204 or 206 to accomplish the desired cutting or ablation of tissue.

In applications where radiofrequency energy is applied to the debulker 14, 14a, the radiofrequency energy may be applied continuously at 100KHz-2MHz, and preferably at
25 about 500KHz (i.e., 70 watts) until the cutting operation is complete. Alternatively, such radiofrequency energy may be delivered intermittently, in pulsed fashion, to avoid necrosis or damage to the adjacent tissue. Preferably, as illustrated graphically in Figures 14a and 14b, when pulsed radiofrequency energy is used in lieu of
30 continuous energy, the duty cycle of the pulsed energy will be optimized to provide efficient tissue cutting while avoiding damage

to surrounding tissue.

Figures 10g-10i show variants of a laser emitting debulker 14b, wherein laser energy is used to cut or vaporize the tissue. The embodiment shown in Figures 10g and 10g' comprises an elongate flexible member having a guidewire lumen 73 extending longitudinally therethrough, and a plurality of longitudinally extending, parallel optical fiber bundles 71 disposed in a generally circular array about the outer perimeter of the member, such optical fiber bundles 71 terminating distally in lenses or other laser emitting surfaces 77 such that a generally conical or annular pattern of laser light is projected from the distal end of the debulker 14b.

Figures 10h and 10h' show an alternative laser emitting debulker 14b' wherein a central laser-transmitting optical fiber bundle 75 extends longitudinally through a portion of the debulker 14b' and terminates proximal to a generally conical cavity 76 formed in the distal end of the debulker 14b'. A stationary prism 77 having a plurality of light guide grooves 78 formed thereabout, is mounted on the distal end of the fiber bundle 75 such that a generally conical pattern of laser light is projected from the prism, through the conical cavity 76 and out of the distal end of the debulker 14b'. An optional suction lumen 79 may be provided in any of these laser embodiments, to enhance their efficiency (as described more fully herebelow) and/ or to aspirate away any residue or tissue particle which become severed during the procedure.

Figures 10i and 10i' show another alternative laser emitting debulker 14b'' wherein the central laser-transmitting optical fiber bundle 75' is rotatable, terminates proximal to a generally conical cavity 76 formed in the distal end of the debulker 14b'. A rotating prism 77 having a single light guide groove 78 formed thereon as shown, is mounted on the distal end of the rotatable fiber bundle 75' such that as laser energy is passed through the optical fiber bundle

75' concurrently with its rotation, a generally conical pattern of laser light will be projected from the rotating prism mounted on the end of the rotating fiber bundle 75', and such laser light pattern will be projected through the conical cavity 76' and out of the distal end of the debulker 14b".

5. Optional Application of Negative Pressure Through Debulker Lumen

In either embodiment of the debulking-type system 10, 10a, negative pressure may be applied through the lumen of the debulker 14, 14a to a) tension the tissue being cut so as to improve the cutting efficiency and/or predictability of the cut and/or b) draw the severed tissue into the lumen of the debulker 14, 14a so as to capture and prevent escape of such severed tissue. Additionally, when suction or negative pressure is applied through the lumen of the debulker 14, 14a, the operator may monitor the amount of negative pressure being generated as an indicator of whether the cutting tip 46, 46a is presently in contact with tissue. In this manner, the operator may promptly discern when the cutting tip 46, 46a has passed fully through the desired tissue and into the opposite blood vessel or other cavernous space.

6. Optional Apparatus for Enabling Operator to Determine When Debulking Operation is Complete

In either debulking-type system 10, 10a, an optional sensor apparatus may be incorporated into the system 10, 10a to provide feedback or signal(s) to enable the operator to determine when the debulking operation is complete so that the advancement or retraction of the debulker 14, 14a may be terminated at an appropriate time. As shown in Figure 16, the sensor apparatus 126 may comprise any suitable type of sensor which will indicate when

the cutting edge 46 of the annular cutting member 42 is no longer in contact with tissue. Examples of the types of sensor apparatus 126 which may be used include sensors which measure impedance, temperature and/or electromagnetic resistance. Additionally, in systems 10, 10a which utilize pulsed energy (Figure 15) in combination with a temperature sensor 126, the temperature sensed by the sensor 126 may be used to manually or automatically (i.e., by a microprocessor or other controller) adjust the duty cycle of the pulsed energy to avoid exceeding a maximum desired temperature (e.g., the thermal necrosis temperature of the tissue—or some other temperature which has been identified as the maximum temperature to which the surrounding tissue may be heated).

7. Optional Apparatus for Controlling the Force Applied by the Debulker

As shown in Figure 16, either of the debulking-type systems 10, 10a may include a force controlling apparatus 128 for controlling the force applied by the debulker 14, 14a upon the tissue being severed. In the particular embodiment shown the debulker 14 has a flexible tubular shaft 40 formed of a proximal segment 40a and a distal segment 40b. The distal segment 40b is slidably received within the lumen of the proximal segment 40a, as shown. The force controlling apparatus 128 comprises a spring 130 which is attached to the proximal and distal portions 40a, 40b of the tube 40 such that, when the distal end of the debulker 14 is pressed against tissue, the spring 130 will compress, thereby normalizing or regulating the force which is applied to the tissue. In embodiments where the debulker emits energy (e.g., radiofrequency energy, resistance heat) first and second energy-transmission contacts 132, 134 such that energy will be emitted from the debulker only when the contacts 132, 134 are in abutment with each other. In this manner, such contact can be

maintained only so long as the debulker 14 is engaging tissue, and when the debulker 14 emerges into the other vessel of open space, the spring 130 will relax causing contacts 132, 134 to separate and the flow of energy through the debulker 14 to cease.

5

B. Dilation-Type Systems

Figures 12-12c show a dilation-type tract enlarging system 10b of the present invention. This dilation-type system 10b generally comprises a) a tubular member 120 having a distal tissue-abutting rim 122, and a lumen 124 extending longitudinally therethrough and b) a shaft 126 having a balloon 128 mounted thereon, a guidewire lumen 130 extending longitudinally therethrough, and an inflation/deflation lumen 132 extending from the proximal end thereof to the interior of the balloon. A guidewire which has previously been passed through the penetration tract which is to be enlarged, is inserted into the distal end of the guidewire lumen 130. Thereafter, with the balloon 128 in its deflated state (Figure 12) and the balloon-bearing portion of the shaft 126 positioned ahead of the tissue abutment rim 122, the system 10b is advanced over the guidewire GW until the tissue abutment rim 122 abuts against or otherwise registers with tissue which surrounds or lies adjacent the proximal end of the penetration tract. Such abutment of the rim 122 against the tissue at the proximal end of the tract will deter further advancement of the system 10b, and will signify to the operator that the balloon 128 has become positioned within the penetration tract. Thereafter, inflation fluid is passed into the balloon 128 through the inflation/deflation lumen 132, causing the balloon 128 to inflate. Such inflation of the balloon serves to dilate the tissue surrounding the penetration tract, thereby accomplishing the desired enlargement of the penetration tract. After the desired dilation of the penetration tract has been completed, the inflation fluid may be withdrawn from the balloon 128 and the system

10b is withdrawn from the body.

C. Tissue-Slicing Type Systems

5 Figures 17-18b show tissue-cutting tract enlarging catheters 10c of the present invention. These tissue cutting catheters 10c comprise a flexible catheter 700 having a tissue cutting distal tip 702a or 702b mounted thereon.

10 In the embodiment shown in Figure 17, the tissue cutting distal tip 702a is a generally cylindrical solid member which has a beveled leading edge 704 and a guidewire lumen 706a extending longitudinally therethrough, as shown.

15 In the embodiment shown in Figures 18a-18c, the tissue cutting distal tip 702b has two (2) tapered lateral surfaces 709a, 709b which converge to form a distal end 710. A central guidewire lumen 706b extends through the distal end 710, as shown.

20 These tissue cutting catheters 10c may be advanced over a guidewire and through a small penetration tract, such that the beveled distal edge 704 or lateral surfaces 706a & 706b will slice or slit the tissue without actually removing any tissue.

D. Two Catheter Tract-Enlarging Systems

25 Figure 19 shows a two-catheter tract enlarging system 10d which comprises comprises a) a first catheter 500 having a tract-enlarging apparatus (not shown) (e.g., a debulker, dialtor or tissue-slicing member of the above-described nature) advancable from an opening 504 at or near the distal end of the first catheter 500, and b) a second catheter 502 which has an anvil member 506 (e.g., an abutable surface or receiving cavity) which is sized and configured to correspond with the leading end of the tract-enlarging apparatus of the first catheter. The first catheter 500 is positioned in one of the anatomical conduits V, and the second catheter is positioned in the

30

other anatomical conduit A, with its anvil member 506 located next to the penetration tract or passageway PT which is to be enlarged. Thereafter, the tract enlarging apparatus (not shown) is advanced through the tract or passageway PT until it registers with (e.g., abutts
5 against or is received with) the anvil member 506 of the second catheter. As the tract enlarging apparatus (not shown) is being advanced, the anvil member 506 serves to provide counterforce against the tissue adjacent the initially formed tract or passageway PT so as to prevent unwanted protrusion or "tenting" of the tissue into
10 the second anatomical conduit A, and to ensure efficient cutting of the tissue in cases where a debulking or tissue slicing type tract enlarging apparatus is used.

Although exemplary embodiments of the present invention have been shown and described, it will be apparent to those having
15 ordinary skill in the art that a number of changes, modifications, or alterations to the invention as described herein may be made, none of which depart from the spirit of the present invention. All such changes, modifications and alterations should therefore be seen as within the scope of the present invention as described herein and
20 recited in the following claims.

25

30

CLAIMS

What is claimed is:

- 3 1. An advanceable debulking system for enlarging an
4 interstitial tract which extends outwardly from the lumen of an
5 anatomical conduit, said system comprising:
6 a counter-traction member which is advanceable, in a first
7 direction, at least partially through the interstitial tract, said
8 counter-traction member having at least one tissue engagement
9 surface formed thereon to engage tissue which is adjacent the
10 interstitial tract, said counter-traction member being useable to apply
11 a force which is directed in a second direction substantially opposite
12 said first direction, upon the tissue which has been engaged by said
13 tissue-engagement member; and,
14 a debulker which is advanceable out of the lumen of the sheath, in
15 the first direction, to remove tissue which lies adjacent the interstitial
16 tract, thereby enlarging the interstitial tract.
- 1 2. The system of Claim 1 wherein the debulker is an elongate
2 member having a lumen which extends longitudinally therethrough,
3 and wherein said counter-traction member extends coaxially through
4 the lumen of the debulker.
- 1 3. The system of Claim 1 wherein the debulker has a distal
2 end, and wherein a tissue-receiving chamber is formed in the distal
3 end of the debulker such that tissue which has been removed by the
4 debulker will enter said tissue-receiving chamber.
- 1 4. The system of Claim 1 wherein a guidewire lumen extends
2 through said counter-traction member such that said counter-traction
3 member may be advanced over a guidewire which extends through
4 the interstitial tract.

1 5. The system of Claim 1 further comprising a sheath having
2 a lumen extending longitudinally therethrough, the lumen of said
3 sheath being sized to permit said debulker and said countertraction
4 member to pass therethrough.

1 6. The system of Claim 5 wherein said sheath has a distal end
2 opening out of which said debulker and said countertraction member
3 are passable.

1 7. The system of Claim 6 wherein said sheath has a side
2 opening out of which said debulker and said countertraction member
3 are passable.

1 8. The system of Claim 7 wherein the lumen of the sheath
2 further comprises a deflector surface which is configured and located
3 to deflect said debulker out of said side opening as said debulker is
4 advanced in the distal direction therethrough.

1 9. The system of Claim 1 wherein said debulker comprises an
2 elongate member having a distal end whereupon an annular cutter
3 is mounted, said annular cutter having a sharpened leading edge so
4 as to sever tissue as it is advanced in the first direction.

1 10. The system of Claim 9 wherein at least the annular cutter
2 of said debulker is rotatable.

1 11. The system of Claim 9 further comprising a motor for
2 rotatably driving at least the annular cutter of said debulker.

1 12. The system of Claim 1 wherein said countertraction
2 member comprises an elongate shaft having a radially expandable

3 tissue-engaging apparatus formed thereon, said radially expandable
4 tissue-engaging apparatus having:

- 5 a) a radially collapsed configuration which is sufficiently small
6 in diameter to pass at least partially through the interstitial tract; and,
7 b) a radially expanded configuration which is sufficiently large
8 in diameter to engage tissue which surrounds the interstitial tract.

1 13. The system of Claim 12 wherein said radially expandable
2 apparatus is selected from the group of radially expandable
3 apparatus consisting of:

- 4 i.) a balloon;
5 ii.) at least one barb;
6 iii.) at least one hook;
7 iv.) a plurality of outwardly curving tissue engagement
8 members, each of said having proximal and distal ends which are
9 attached to the shaft and outwardly curving mid-sections, the mid
10 sections of said tissue engagement members being curved
11 outwardly from said shaft when said
12 v.) a plurality of splayable tissue engagement members
13 having distal ends which are unattached to the shaft of the
14 counter-traction member and positioned at spaced apart locations
15 thereabout, the distal ends of said tissue engagement members
16 being splayable outwardly from the shaft when in their radially
17 expanded configuration; and,
18 vi.) a resilient tubular member which has a radially flared distal
19 end, the flared distal end of said resilient tubular member being
20 advanceable, in the first direction, from the distal end of the shaft of
21 said counter-traction member.

1 14. The system of Claim 1 wherein the debulker further
2 comprises: at least one energy-transmitting member which may be

3 connected to an energy source, said energy transmitting member
4 being operative to transmit energy from an energy source connected
5 thereto, to a location on the debulker at which said energy will
6 enhance the ability of the debulker to remove tissue.

1 15. The system of Claim 14 wherein the energy-transmitting
2 member is a member which transmits radio-frequency energy.

1 16. The system of Claim 15 further comprising: a
2 radio-frequency generator attached to said energy-transmitting
3 member.

1 17. The system of Claim 15 wherein said debulker is an
2 elongate member which has a tissue-severing surface formed on the
3 distal end thereof, and wherein the energy-transmitting member is
4 positioned and constructed to transmit radiofrequency energy to the
5 tissue-severing surface of the debulker.

1 18. The system of Claim 17 wherein the tissue-severing
2 surface comprises a leading edge formed on an annular cutting
3 member.

1 19. The system of Claim 1 further comprising: A dilator formed
2 on the distal end of said counter-traction member to dilate the
3 interstitial tract as the counter-traction member is advanced
4 therethrough.

1 20. The system of Claim 19 wherein the dilator is a
2 frusto-conical dilator member having a distal end of a first diameter
3 and a proximal end of a second diameter larger than said first
4 diameter.

1 21. The system of Claim 19 wherein: the counter-traction
2 member has a longitudinal axis; and, an annular tissue-abutment
3 surface is formed on the proximal end of the frus which is generally
4 perpendicular to the longitudinal axis of the counter-traction member.

1 22. The system of Claim 21 wherein: an annular cutting
2 member is formed on the distal end of the debulker; and, the annular
3 tissue abutment surface comprises a cutting plate which is sized,
4 configured and positioned such that when the debulker is advanced
5 in the first direction, the annular cutting member will register with the
6 cutting plate.

1 23. A retractable debulking system for enlarging an
2 interstitial tract which extends outwardly from the lumen of an
3 anatomical conduit, said system comprising:
4 a tubular, proximal counter-force member which has at least
5 one tissueengaging surface formed on the distal end thereof, said
6 proximal counter-force member being advanceable into the lumen of
7 the anatomical conduit from which said interstitial tract extends such
8 that its tissue-engaging surface engages tissue adjacent the
9 interstitial tract; and, a retractable debulker which is advanceable out
10 of the distall end of the proximal counter-force member and through
11 the interstitial tract in a first direction, said debulker being
12 subsequently retractable in a second direction opposite said first
13 direction, said debulker having a at least one tissue removing
14 surface formed on the proximal end thereof to remove tissue located
15 adjacent the interstitial tract as the debulker is retracted in the
16 second direction through the interstitial tract; said proximal
17 counter-traction member being operative to apply a counterforce in
18 the first direction against the tissue adjacent the interstitial tract, as

19 the debulker is being retracted in the second direction to remove said
20 tissue.

1 24. The system of Claim 23 wherein the retractable debulker
2 has aproximal tissue cutting surface, and wherein a tissue-receiving
3 chamber is formed with the debulker adjacent to said tissue cutting
4 surface, such that tissue which has been removed by the debulker
5 will enter said tissue-receiving chamber.

1 25. The system of Claim 23 wherein a guidewire lumen
2 extends through said retractable debulker such that said retractable
3 debulker may be advanced over a guidewire which extends through
4 the interstitial tract.

1 26. The system of Claim 23 further comprising a sheath
2 having a lumen extending longitudinally therethrough, the lumen of
3 said sheath being sized to permit said debulker and said
4 countertraction member to pass therethrough.

1 27. The system of Claim 26 wherein said sheath has a distal
2 end opening out of which said debulker and said countertraction
3 member are passable.

1 28. The system of Claim 26 wherein said sheath has a side
2 opening out of which said debulker and said countertraction member
3 are passable.

1 29. The system of Claim 28 wherein the lumen of the sheath
2 further comprises a deflector surface which is configured and located
3 to deflect said debulker out of said side opening as said debulker is
4 advanced in the distal direction therethrough.

1 30. The system of Claim 22 wherein said retractable debulker
2 comprises an elongate member having a proximal end whereupon
3 an annular cutter is mounted, said annular cutter having a sharpened
4 leading edge so as to sever tissue as it is retracted the proximal
5 direction through the penetration tract.

1 31. The system of Claim 30 wherein at least the annular cutter
2 of said retractable debulker is rotatable.

1 32. The system of Claim 9 further comprising a motor for
2 rotatably driving at least the annular cutter of said debulker.

1 33. A laser debulking apparatus, useable for enlarging an
2 interstitial penetration tract, said apparatus comprising:
3 an elongate flexible member having a guidewire lumen
4 extending longitudinally therethrough;
5 a plurality of laser transmitting members extending
6 longitudinally through said flexible member, said laser transmitting
7 members being disposed in a generally annular array,
8 each of said laser transmitting members having a distal end
9 associated with a laser light transmitting surface whereby laser light
10 from that laser transmitting member will be projected from said
11 flexible member, such that when laser energy is concurrently passed
12 through all of said laser transmitting members, a generally annular
13 pattern of laser light will be projected from said apparatus.

1 34. The apparatus of Claim 33 further comprising a suction
2 lumen extending through said flexible member to apply suction to the
3 area into which said pattern of laser light is projected.

1 35. A laser debulking apparatus, useable for enlarging an
2 interstitial penetration tract, said apparatus comprising:
3 an elongate flexible member having a guidewire lumen
4 extending longitudinally therethrough;
5 a laser transmitting member extending longitudinally through
6 said flexible member;
7 a prism having at least one light guide groove formed therein,
8 said prism being rotatably positioned on the end of said laser
9 transmitting member such that laser energy which passes through
10 said laser transmitting member will pass into said prism and will be
11 caused by said at least one light guide groove and the concurrent
12 rotation of said prism, to be projected in a generally conical pattern
13 from said apparatus.

1 36. The apparatus of Claim 35 further comprising a suction
2 lumen extending through said flexible member to apply suction to the
3 area into which said pattern of laser light is projected.

1 37. The apparatus of Claim 35 wherein said laser transmitting
2 member is rotatable, and wherein said prism is mounted on the distal
3 end of said laser transmitting member so as to rotate concurrently
4 with said laser transmitting member.

1 38. A laser debulking apparatus, useable for enlarging an
2 interstitial penetration tract, said apparatus comprising:
3 an elongate flexible member having a guidewire lumen
4 extending longitudinally therethrough;
5 a laser transmitting member extending longitudinally through
6 said flexible member;
7 a prism having a plurality of light guide grooves formed
8 therein, said light guide grooves being disposed in a generally

9 annular array, said prism being positioned on the end of said laser
10 transmitting member such that laser energy which passes through
11 said laser transmitting member will pass into said prism and will be
12 caused by said plurality light guide grooves to be projected in a
13 generally conical pattern, from said apparatus.

1 39. The apparatus of Claim 38 further comprising a suction
2 lumen extending through said flexible member to apply suction to the
3 area into which said pattern of laser light is projected.

INTERNATIONAL SEARCH REPORT

International application No.
PCT/US99/07518

A. CLASSIFICATION OF SUBJECT MATTER

IPC(6) : A61D 17/32
US CL : 606/96, 159, 184

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

U.S. : 606/96, 159, 184

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
A, P	US 5,830,222 A (MAKOWER) 03 November 1998, cols. 1-10.	1-39
A	US 5,556,377 A (ROSEN et al.) 17 September 1996, cols. 1-12.	1-39
A	US 5,531,677 A (LUNDQUIST et al.) 02 July 1996, cols. 1-15.	1-38

☐ Further documents are listed in the continuation of Box C. ☐ See patent family annex.

* Special categories of cited documents:	*T* later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
A document defining the general state of the art which is not considered to be of particular relevance	*X* document of particular relevance, the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
E earlier document published on or after the international filing date	*Y* document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
L document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)	*Z* document member of the same patent family
O document referring to an oral disclosure, use, exhibition or other means	
P document published prior to the international filing date but later than the priority date claimed
